1 Introduction

2 Clustering

Clustering is the act of separating data into discrete groups to help analysis and prediction.

2.1 k-means

2.2 k++means

2.3 Initialization Effects

2.4 Comparisons

2.5 Image Segmentation Experiments

3 Time Series Models

Time Series Models are used for a number of analytical and predictive purposes, such as modeling fluctuating inventory levels, commodity prices, and stock prices.

3.1 Box-Jenkins Methodology

A time series can contain any of the following components:

- Trend
 - Seasonality
 - Cyclic
 - Random
1. Condition data and select a model
 - Identify and account for any trends or seasonality in the time series.
 - Examine the remaining time series and determine a suitable model.
 2. Estimate the model parameters
 3. Assess the model and return to step one if necessary

3.2 ARIMA Models

ARIMA Models are a combination of Autoregression, Integration, and Moving Average models. They are denoted by $ARIMA(p,d,q)$, where p =autoregression factor, d =level of integration, and q =moving average factor

3.3 ARIMA Variable Selection

4 Conclusion

5 Figures & Tables
